

# CLIMATE-DRIVEN VULNERABILITY ASSESSMENT OF HAMILTON'S URBAN FOREST: A Ward-Level Resilience Framework for 2030, 2050, and 2080

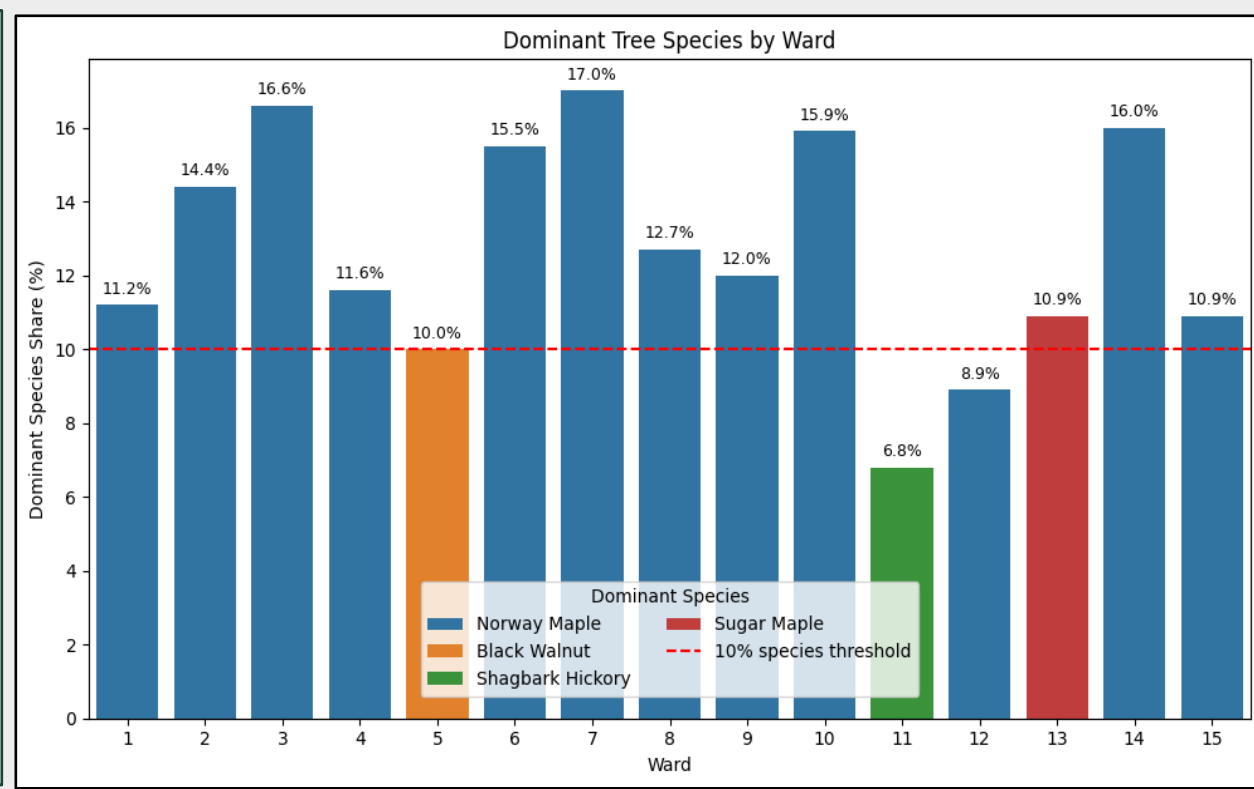

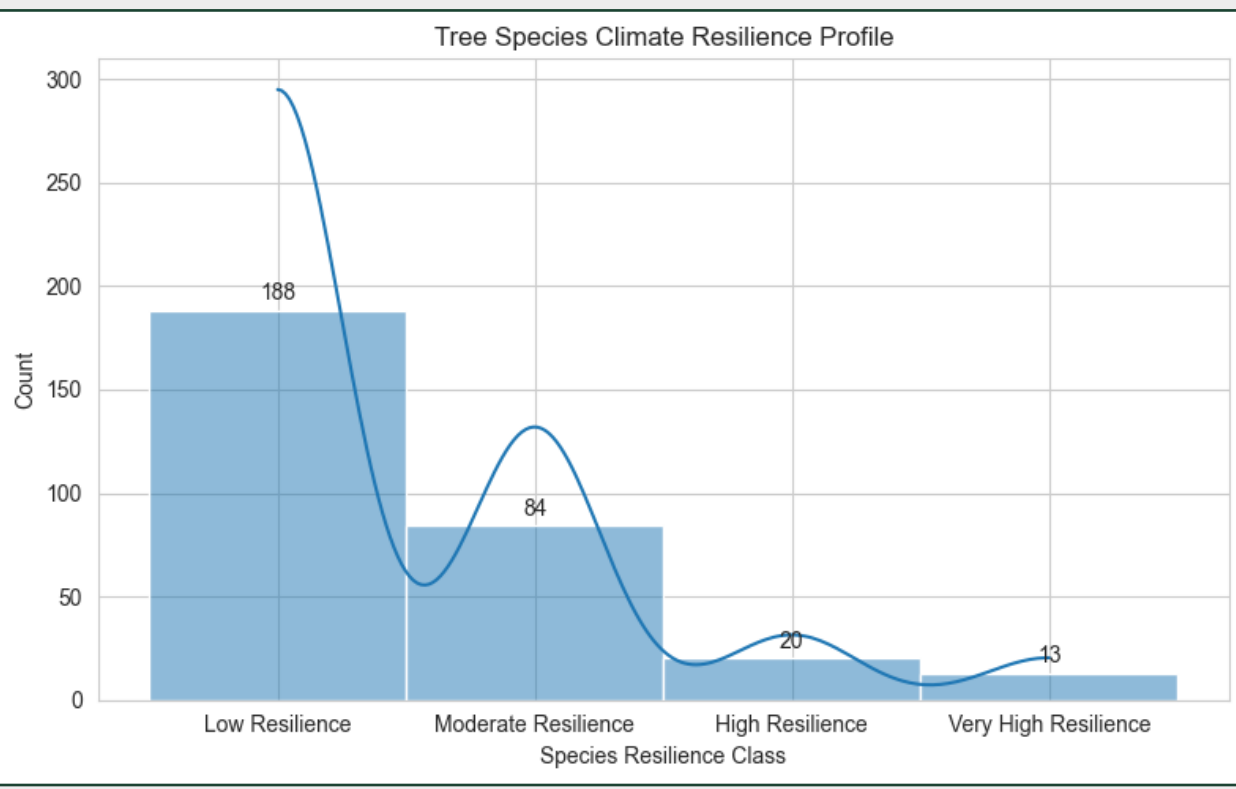

University of Niagara Falls's Students: Susana Carolina Romero Aparicio, Su Myat Aung, Tessy Ramirez, Yi Xin

Supervisor: PhD. Omid Isfahaniamdari

## The City Problem

- 275,156 trees inventory, 15 wards analyzed
- Extreme Heat & Flooding identified as Priority Risks
- Norway Maple (Invasive Species) Dominance
- Summer Heat +4.47°C Projected Increase by 2080

## SPECIES VULNERABILITY SCORE (IPCC AR5 FRAMEWORK)

### Exposure

Magnitude of climate stress  
 Extreme Heat Intensity ( $\Delta TXx$ ) x (1 + Heat Index)  
 ISA Heat Index =  $\sum (\text{Population\_Category} \times \text{Impervious Surface Weight})$

### Sensitivity (1 - Resilience score)

Susceptibility to climate stress  
 Resilience = Heat ( $\Delta HS \text{ Temp} > 30^\circ C$ ), Hydroclimate (Drought + Saturated Soil Tolerance), Pollution Tolerance, Climate Suitability

### Adaptive Capacity

Ecosystem ability to recover  
 DBH (Diameter at Breast Height)

## RESEARCH QUESTIONS

### RQ1: Climate Exposure

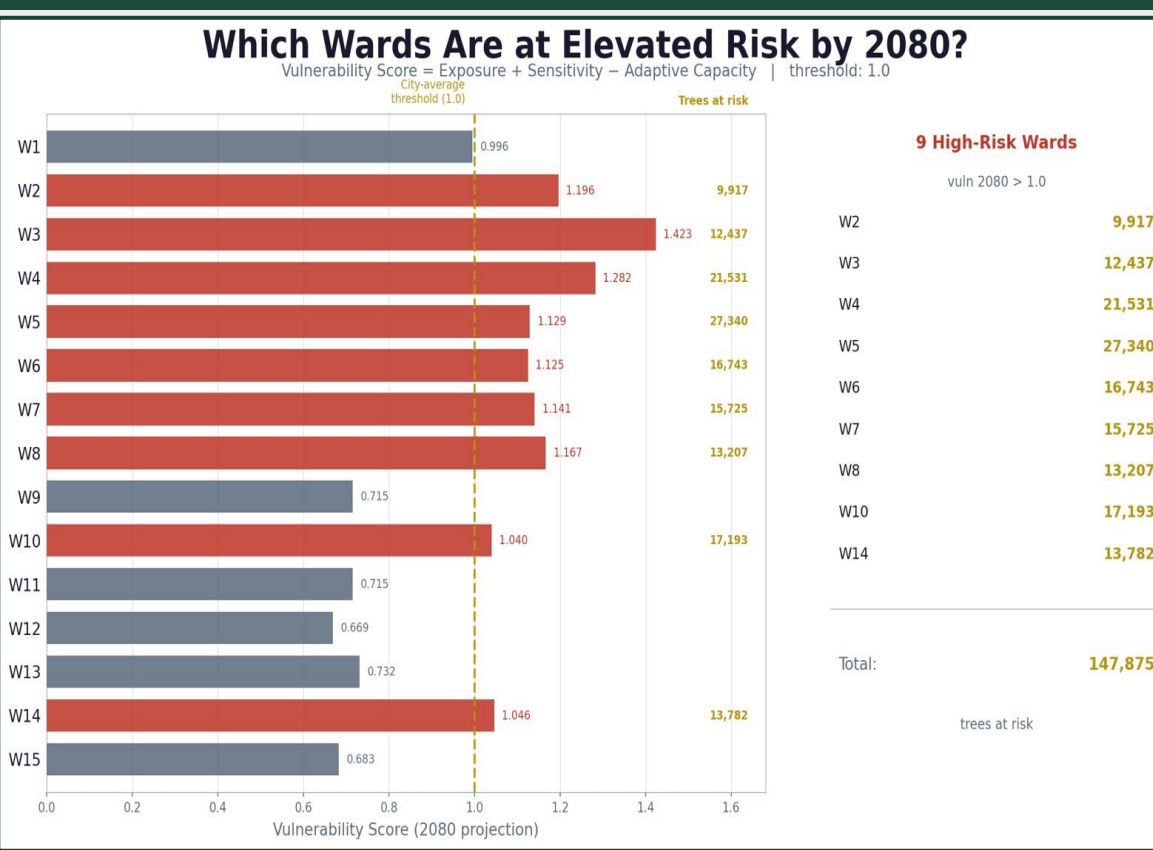

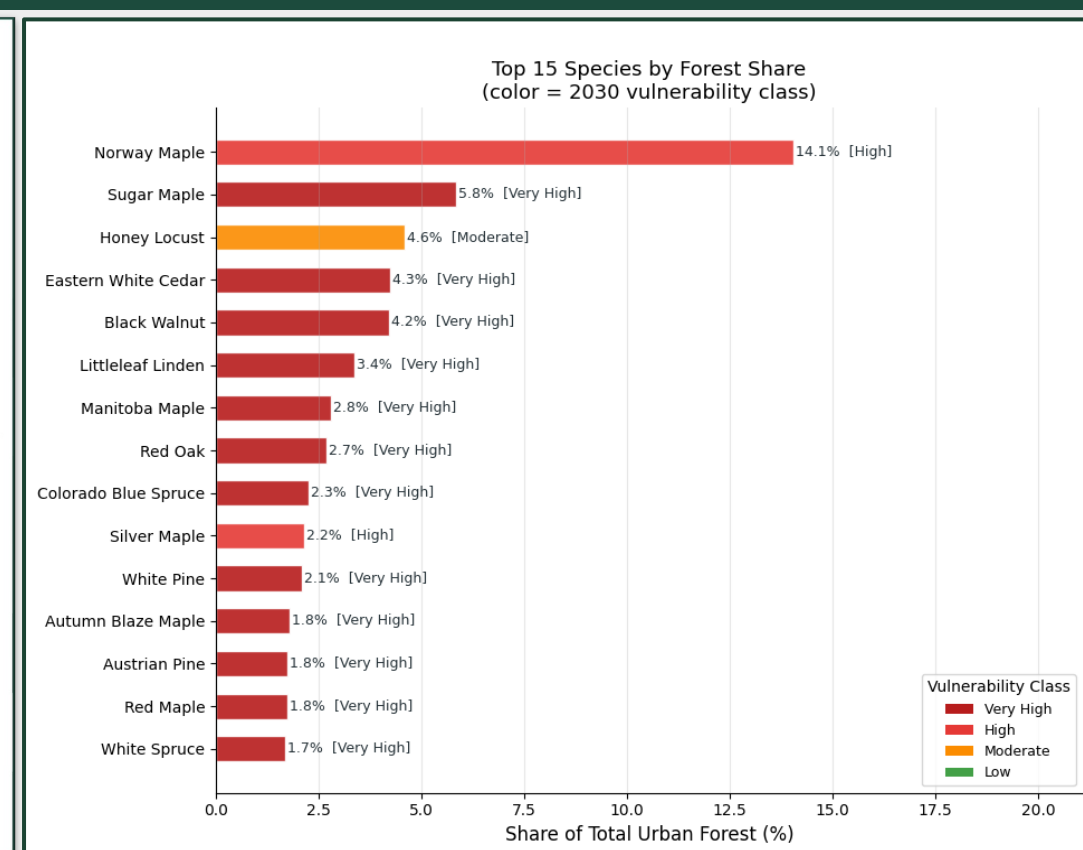

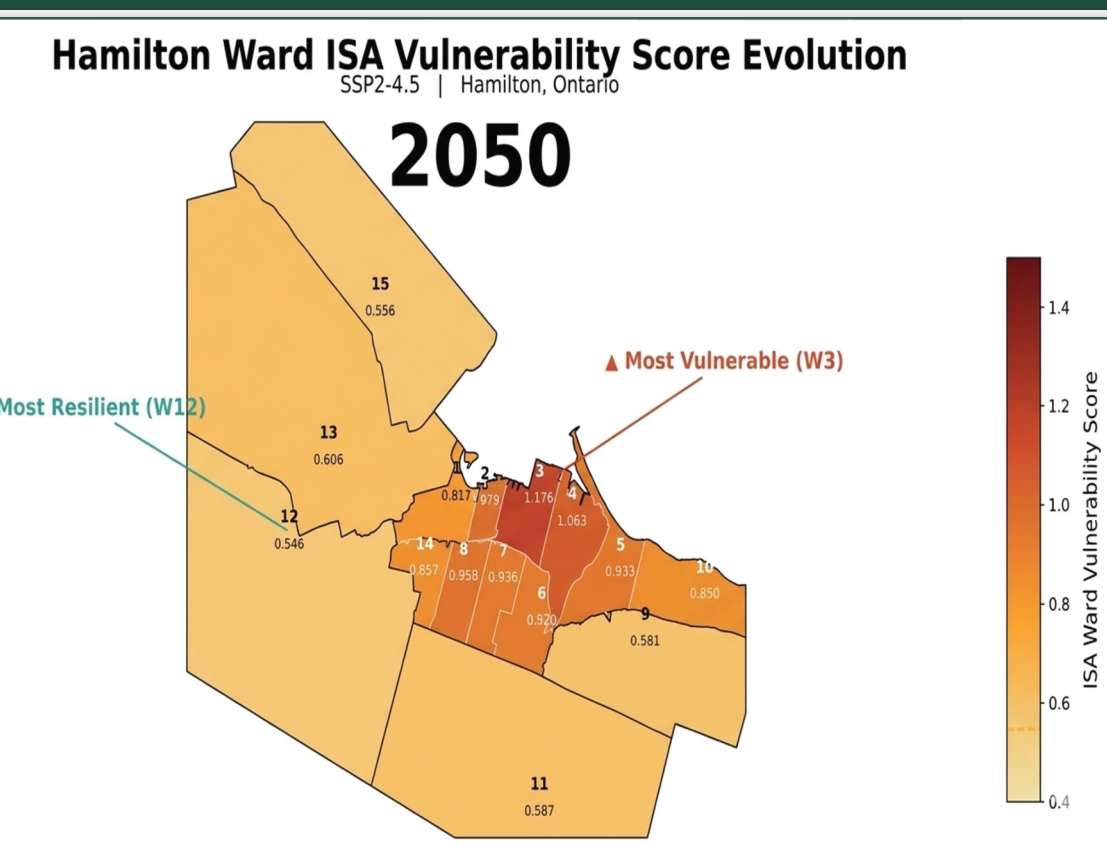

Does current species composition provide sufficient resilience to future climate conditions?

### RQ3: Spatial Risk Concentration

How vulnerable is Hamilton's current urban forest to future climate change?

### RQ2: Species Resilience

Which wards and dominant species exhibit the highest climate vulnerability?

## 10/20/30 RULE FOR BIODIVERSITY

No single species >10% | No genus >20% | No family >30%

**Hamilton's Violations:**

- Norway Maple exceeds 10% species threshold
- Acer genus exceeds 20% in 14 of 15 wards
- Ward 4: 31% Acer dominance
- Sapindaceae family approaching 30% limit

**Fraxinus Species (Ash Trees)**  
9,170 trees (3.3% of inventory)

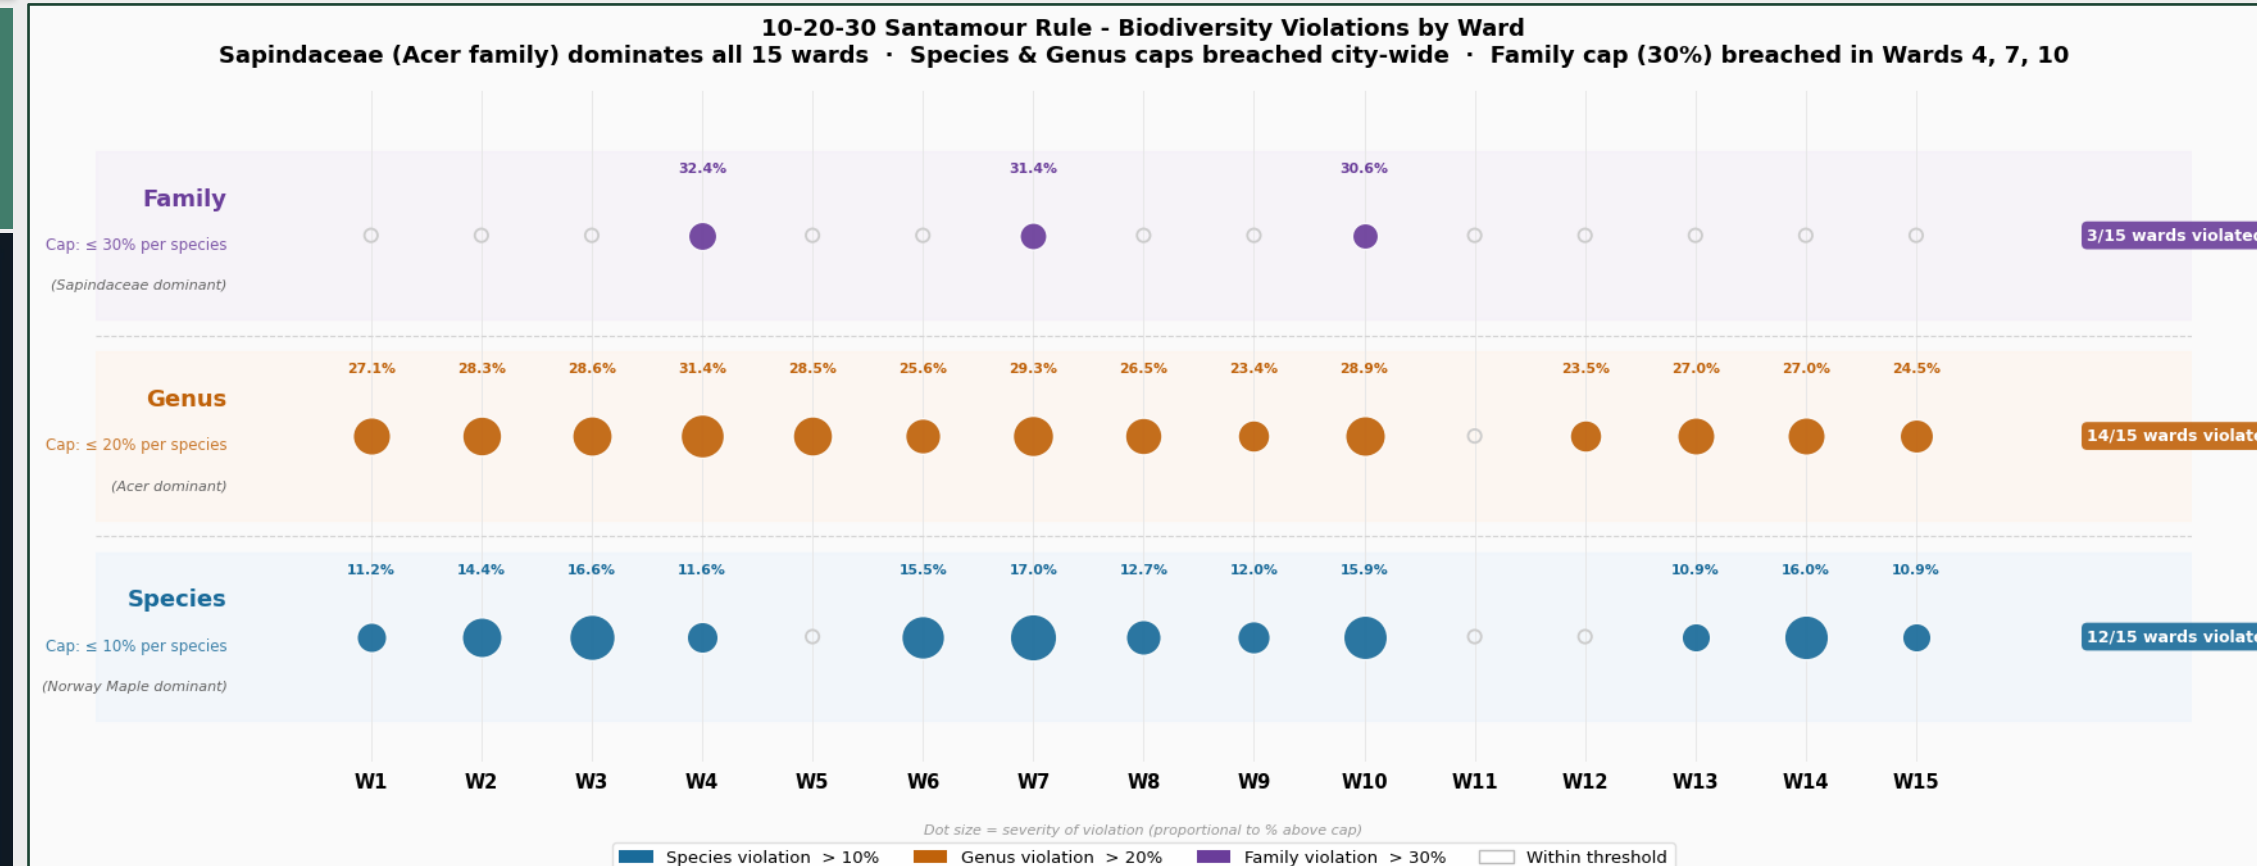

Highly vulnerable to Emerald Ash Borer  
Excluded from recommendations

Extreme pest susceptibility eliminates future planting viability

**Norway Maple (Acer platanoides)**  
11.9% of total urban forest

Exceeds 10% Santamour threshold  
Major vulnerability contributor

Acer genus exceeds 20% threshold in 14 of 15 wards. Dominant urban species contributing significantly to overall forest vulnerability.

### Replanting Priority – Score Composition

Replanting Priority (t) =

0.40 x Built Environment Stress + 0.35 x Climate Vulnerability (t)  
 + 0.15 x Low Diversity Pressure + 0.10 x Biodiversity Pressure

**Built Environment Stress (40%) – the dominant factor.**  
 Combines road stress (arterial road share) and zoning stress (built land share). Trees in dense urban environments face compounded heat, pollution, and physical root stress.

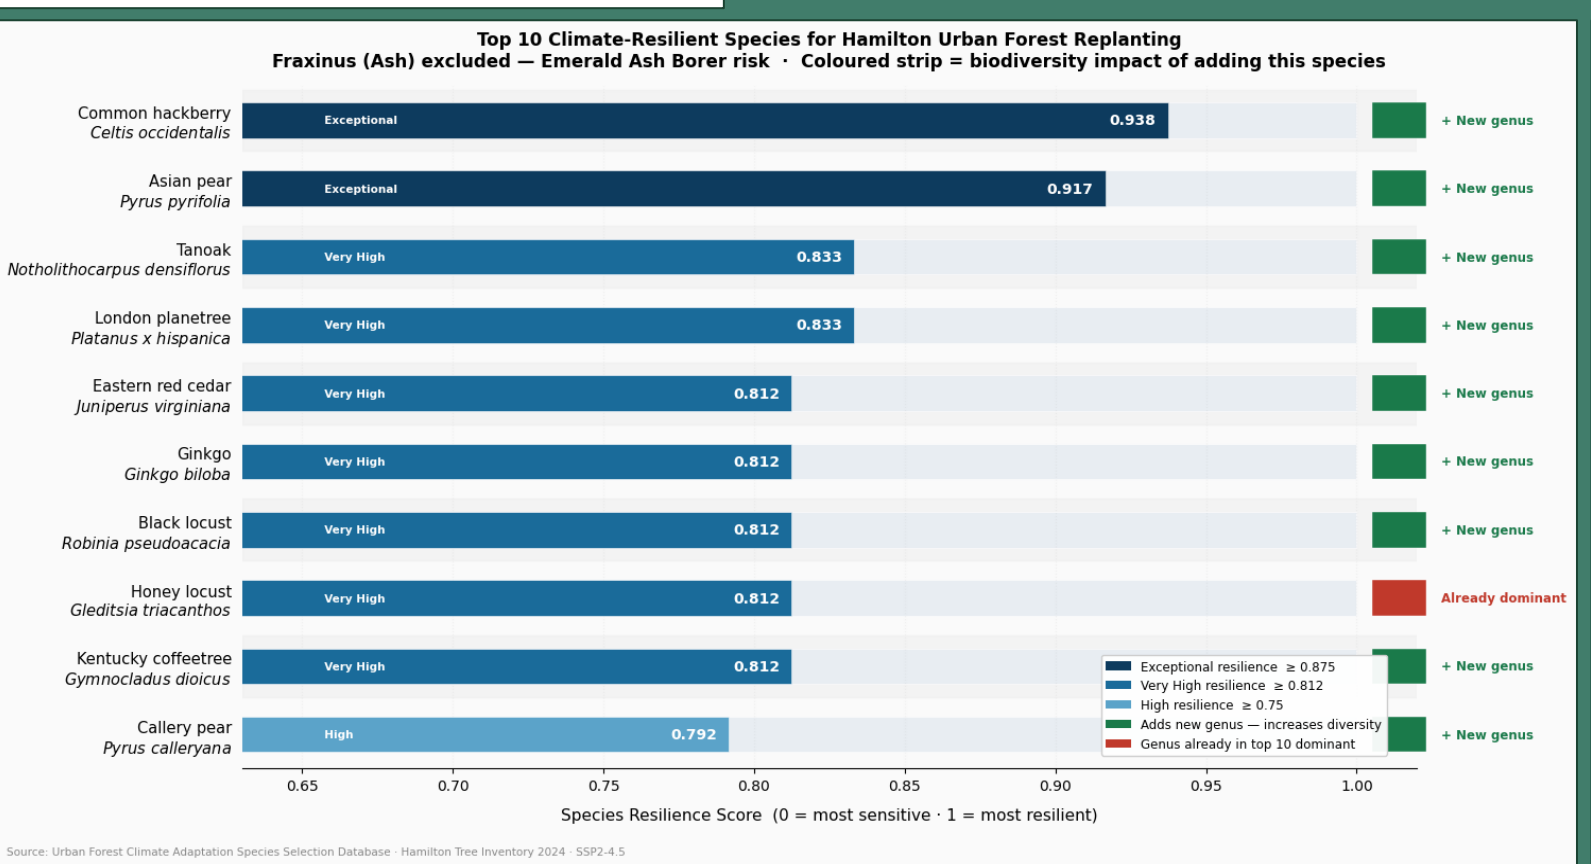

**Climate Vulnerability (35%)**  
 The ISA-adjusted vulnerability scores from Step 4, time-indexed to 2030, 2050, or 2080.

**Low Diversity Pressure (15%)**  
 Wards with fewer total species have less ecological buffer. The fewer species present, the higher the pressure to diversify.

**Biodiversity Pressure (10%)**  
 Species and genus dominance violations from the Santamour analysis. High Acer monoculture concentration pushes this score up.

## STRATEGIC CLIMATE ADAPTATION PLAN

- Prioritize Replanting Climate-resilient species for Ward 3, 4, 7
- Prioritize Incentives for Private Planting and Streetscape Retrofits in Wards 2 & 7 (where Public & Private canopy Coverage < 20%)
- Diversify Species Portfolio & Enhance Ecosystem Resilience
- Common hackberry (0.938) & Asian pear (0.917) - Highest resilience.
- Integrate Resilience Scoring into City of Hamilton Urban Forest Strategy Implementation

THE BIGGEST RISK to Urban Forest is NOT Climate Alone! Strategic Coordinated Action Across Vulnerable Wards, Species Diversification, and Policy Integration is Required!
